

Microeconomic Analysis Problem Set 4

1a Let x_c denote the contestant's initial choice, and x_h denote the host's choice, i.e. the door the host opens, and x_p denote the prize choice, i.e. the door that hides the prize.

Suppose that $x_p = A$, suppose further that $x_c = A$, then ~~$x_h = B$~~ $x_h = B$ with probability $\frac{1}{3}$ and $x_h = C$ with probability $\frac{2}{3}$, i.e. $P(x_h = B) = \frac{1}{3}$
 $P(x_h = C | x_p = A, x_c = A) = \frac{2}{3}$ and $P(x_h = C | x_p = A, x_c = A) = \frac{1}{3}$

continue
suppose to suppose that $x_p = A$, suppose further instead that ~~$x_c = B$~~ $x_c = B$, then $x_h = C$ with certainty, i.e. $P(x_h = C | x_p = A, x_c = B) = 1$ and $P(x_h = B) = 0$. By symmetry, $P(x_h = B | x_p = A, x_c = C) = 1$.

continue to suppose that $x_p = A$.

$$\begin{aligned} P(x_h = B | x_p = A, x_c = C) &= P(x_p = A \cap x_c = C \cap x_h = B) / P(x_h = B) \\ &\text{suppose that} \\ &P(x_p = A \cap x_c = A, x_h = B) \\ &= P(x_p = A \cap x_h = B | x_c = A) / P(x_h = B | x_c = A) \\ &= \frac{1}{6} / \frac{1}{2} \\ &= \frac{1}{3} \end{aligned}$$

$$\begin{aligned} P(x_p = C | x_c = A, x_h = B) &= P(x_p = C \cap x_h = B | x_c = A) / P(x_h = B | x_c = A) \\ &= \frac{1}{3} / \frac{1}{2} \\ &= \frac{2}{3} \end{aligned}$$

$$\begin{aligned} P(x_p = A | x_c = A, x_h = B) &= P(x_p = A \cap x_h = B | x_c = A) / P(x_h = B | x_c = A) \\ &= (\frac{1}{3} \times \frac{1}{2}) / \frac{1}{2} \\ &= P(x_p = A | x_c = A) P(x_h = B | x_p = A, x_c = A) / P(x_h = B | x_c = A) \\ &= (\frac{1}{3} \times \frac{1}{2}) / (\frac{1}{2}) \end{aligned}$$

where $P(x_h = B | x_c = A) = \frac{1}{2}$ follows by symmetry from B's being chosen arbitrarily, i.e. $P(x_h = C | x_c = A) = P(x_h = B | x_c = A)$ and given $P(x_h = A | x_c = A) = 0$,
 $P(x_h = B | x_c = A) = P(x_h = C | x_c = A) = \frac{1}{2}$
 $= \frac{1}{3}$

$$\begin{aligned} P(x_p = C | x_c = A, x_h = B) &= 1 - P(x_p = A | x_c = A, x_h = B) \\ &\text{given that } P(x_p = B | x_c = A, x_h = B) = 0 \text{ and } x_p \in \{A, B, C\} \\ &= \frac{2}{3} \end{aligned}$$

Since ~~x_c, x_h , and x_p~~ x_c and x_h were chosen arbitrarily, by generalization,

$$\begin{aligned} P(x_p = x_c | x_c, x_h \neq x_c) &= \frac{1}{3} \\ P(x_p \neq x_c | x_c, x_h \neq x_c) &= \frac{2}{3} \end{aligned}$$

switching doubles the contestant's probability of winning the prize.

The host's opening one door "collapses" the probability mass that the prize is behind ~~that~~ ~~the~~ door into the ~~one~~ of the two unchosen doors onto the remaining unchosen and unopened door, rather than distributing the probability that the prize is behind the opened door evenly between the two unopened doors.

b) $x_H = B$ is more informative than merely revealing that $x_P \neq B$. The probability that $x_H = B$ given that ~~$x_C = A$ and $x_P = A$~~ is $\frac{1}{2}$ while the probability that $x_H = B$ given that $x_C = A$ and $x_P = C$ is 1. Given that $(x_C = A \text{ and } x_P = A)$ and $(x_C = A \text{ and } x_P = C)$ are equally likely have equal prior probability, by Bayes rule, $x_H = B$ should result in a positive increase in the posterior probability of $x_P = C$ and a decrease in the (relative) posterior probability of $x_P = A$.

$$\text{2a) Let } L_1 = [0.9, 0.1; 0.8, 4], L_2 = [1, 1]$$

Let U be the utility representation of ~~A's~~ A's preferences over lotteries.

Given that A has expected utility preferences,
 $U(L) = \sum_{i=1}^n p_i U(x_i)$, where $L = [p_1, \dots, p_n; x_1, \dots, x_n]$

$$U(L_2) = U(L_1) = 0.9U(0.8) + 0.1U(4) = 0.1$$

$$U(L_2) = 1U(1) = 0.1, U(1) = 0.1$$

$$b) 4U(4) = 0.4 \leftarrow U(4) = 1$$

$$15/16 U(0.8) + 1/16 U(4) = 1/16$$

$$U(15/16 \times 0.8 + 1/16 \times 4) = U(1) = 0.1 \cancel{\rightarrow 1/16}$$

$$15/16 U(0.8) + 1/16 U(4) < U(15/16 \times 0.8 + 1/16 \times 4)$$

U is strictly concave, A is risk-averse

consider $L' = [15/16, 1/16; 0.8, 4]$

$$EV(L') = 15/16 \times 0.8 + 1/16 \times 4 = 1$$

$$\text{From } (a), \cancel{U(L') = 1}$$

$$U(L') = 1/16 \times U([1; EV(L')]) = 0.1$$

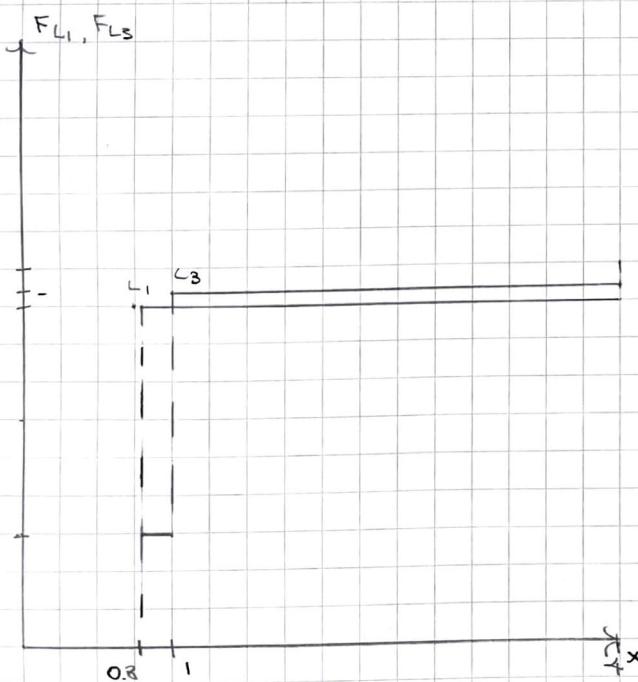

$$[1; EV(L')] \succ L'$$

is not possible to tell whether A is risk-averse or not strict

Assuming that A's Bernoulli utility is well-behaved,
~~A is risk~~ it is strictly concave, and A is risk-averse.

[is this assumption implicit in EU preferences?]

$$c) \text{ Let } L_3 = [0.3, 0.04, 0.06; 0.8, 1, 4]$$

By inspection of the cumulative distribution functions F_{L_1} and F_{L_3} , neither L_3 FOSO L_1 nor $L_3 \succ_{FOSO} L_1$ since neither F_{L_3} lies entirely below F_{L_1} nor F_{L_3} lies entirely below F_{L_1} ; $L_3 \succeq_{FOSO} L_1$ since F_{L_3} crosses F_{L_1} once from below.

$$\Delta \text{ Let } L_4 = [\frac{1-p}{1-p}, p; 1, 4]$$

$$U(L_4) = pU(4) + (1-p)U(\frac{1}{1-p}) = 0.1 + 0.9p$$

$$U(L_3) = 0.3U(0.8) + 0.04U(1) + 0.06U(4) = 0.064 + 0.06 = 0.124$$

$$p = 0.024 / 0.9 = 2/75$$

3 *

Let F and G be cumulative distribution functions on $[a, b] \subset \mathbb{R}$, i.e. $F(a) = G(a) = 0$, ~~$F(b) = G(b) = 1$~~ , and each of F and G is weakly increasing.

Suppose that $F \succ_{LR} G$ in the domain $[a, b]$.

then by definition of LR dominance,

$F'(x)/G'(x)$ is weakly increasing in the domain $[a, b]$

then $\forall x < z < y < b \in [a, b]: F(x)/G'(x) \geq F'(z)/G'(z) \geq F'(y)/G'(y)$

Given that each of F and G is strictly increasing,

~~$F'(x) \geq 0$ and $G'(x) \geq 0$~~ .

so $\forall x < z < y < b \in [a, b]: F'(x)G'(z) \geq F'(z)G'(x)$

$$\int_{z=a}^x F'(x)G'(z) dz = F'(x) \int_{z=a}^x G'(z) dz = F'(x)G(x)$$

$$\int_{y=z}^x F'(z)G'(x) dz = G'(x) \int_{y=z}^x F'(z) dz = G'(x)F(x)$$

then $F'(x)G(x) \geq G'(x)F(x)$

$$\int_{x=z}^b F'(x)G'(z) dx = G'(z) \int_{x=z}^b F(x) dx = G'(z)(F(b) - F(z))$$

$$= G'(z)(1 - F(z))$$

$$\int_{x=z}^b F'(z)G'(x) dx = F'(z) \int_{x=z}^b G'(x) dx = F'(z)(G(b) - G(z))$$

$$= F'(z)(1 - G(z))$$

then $G'(z)(1 - F(z)) \geq F'(z)(1 - G(z))$

Recurrence,

$$F(x) \leq G(x) \quad F'(x)/G'(x)$$

$$1 - F(z) \geq (1 - G(z)) \quad F'(x)/G'(x)$$

Suppose that $F'(x)/G'(x) < 1$, then $F(x) \not\succ G(x)$

Suppose that $F'(x)/G'(x) = 1$, then

$F(x) \leq G(x)$ and $1 - F(x) \geq 1 - G(x) \Rightarrow F(x) = G(x)$

Suppose that $F'(x)/G'(x) > 1$, then

$$1 - F(x) \geq 1 - G(x) \Rightarrow F(x) < G(x)$$

so for all $x \in [a, b]$ $F(x) \not\succ G(x)$ and for some such x

$F(x) \not\succ G(x)$, so $F \not\succ G$

- 4a Let \succeq denote A's preferences over lotteries. Given that A has EU preferences, there is some function U that represents \succeq such that $U(L) = \sum_{i=1}^n p_i U(x_i)$ for some U , where $L = [p_1, \dots, p_n; x_1, \dots, x_n]$. Let $L(x)$ denote the lottery given x .

$$L(x) = [\alpha, 1-\alpha; w+2x, w-x]$$

$$U(L(x)) = \alpha U(w+2x) + (1-\alpha)U(w-x)$$

A's maximisation problem is $\max_x U(L(x))$

$$\text{FOC: } \frac{\partial U(L(x))}{\partial x} \Big|_{x=x^*} = 2\alpha U'(w+2x^*) - (1-\alpha)U'(w-x^*) = 0$$

By implicit differentiation wrt α
 ~~$\frac{\partial U'(w+2x^*)}{\partial \alpha}$~~

$$\begin{aligned} &\text{By implicit differentiation wrt } \alpha \\ &2U'(w+2x^*) + 4\alpha U''(w+2x^*) \frac{\partial x^*}{\partial \alpha} \\ &+ U''(w-x^*) \frac{\partial x^*}{\partial \alpha} \\ &+ U'(w-x^*) - \alpha U''(w-x^*) \frac{\partial x^*}{\partial \alpha} \\ &= 0 \end{aligned}$$

Rearranging,

$$[4\alpha U''(w+2x^*) + (1-\alpha)U''(w-x^*)] \frac{\partial x^*}{\partial \alpha} = -2U'(w+2x^*) - U'(w-x^*)$$

Supposing that A prefers more wealth to less, U is strictly increasing, i.e. ~~$\forall x: U'(x) > 0$~~ . Given that A is risk averse, ~~$\forall x: U''(x) < 0$~~ . $\alpha \in [0, 1]$
Then $\frac{\partial x^*}{\partial \alpha} > 0$

$$\text{SOC: } \frac{\partial^2 U(L(x))}{\partial x^2} \Big|_{x=x^*} = 4\alpha U''(w+2x^*) + (1-\alpha)U''(w-x^*) < 0$$

The FOC is satisfied at the FOC is satisfied at a local maximum.

$x^* = \arg\max_x U(L(x))$ increases with increasing α , the higher the value of α , the higher the value x A optimally chooses.

- b $\forall r \in (0, 1) : \text{CRRA}(r) \Rightarrow U(x) = x^{1-r}$

$$U'(x) = (1-r)x^{-r}$$

$$\text{FOC: } \frac{\partial U(L(x))}{\partial x} \Big|_{x=x^*} = 2\alpha(1-r)(w+2x^*)^{-r} - (1-\alpha)(1-r)(w-x^*)^{-r} = 0$$

$$2\alpha(w+2x^*)^{-r} = (1-\alpha)(w-x^*)^{-r}$$

$$(2\alpha)^{-r} (w+2x^*) = (1-\alpha)^{-r} (w-x^*)$$

$$[2(2\alpha)^{1/r} + (1-\alpha)^{1/r}] x^* = [(1-\alpha)^{1/r} + (2\alpha)^{1/r}] w$$

$$x^* = \frac{[(1-\alpha)^{1/r} - (2\alpha)^{1/r}] w}{[(1-\alpha)^{1/r} + 2(2\alpha)^{1/r}]}$$

$$\frac{1}{r} \rightarrow \frac{1}{r} \Rightarrow \frac{1}{r} \rightarrow \frac{1}{r} \Rightarrow \frac{1}{r} \left(\frac{1}{r} - \frac{1}{r} \right) \frac{1}{r} \frac{1}{r}$$

$U''(x) = -r(1-r)x^{-1-r} < 0$, so the SOC holds and the FOC is satisfied at a local maximum.

For $\alpha \leq \frac{1}{3}$, $(w+2x^*)^{-r} \geq (w-x^*)^{-r}$, $w+2x^* \leq w-x^*$, $x^* \leq 0$.

Given that $x \in [0, w]$, for $\alpha \leq \frac{1}{3}$, A's maximisation problem has a corner solution, $x^* = 0$. For such α , x^* (weakly) decreases with increasing r .

For $\alpha > \frac{1}{3}$, $\frac{(w+2x^*)^{-r}}{(w-x^*)^{-r}}$

$$(2\alpha)^{-r} (w+2x^*) = (1-\alpha)^{-r} (w-x^*),$$

$$\frac{w+2x^*}{w-x^*} = \frac{(1-\alpha)^{-r}}{(2\alpha)^{-r}} = (1-\alpha)^{-r} (2\alpha)^{-r}$$

$$\frac{2\alpha}{1-\alpha} \geq 1, \quad \frac{1-\alpha}{2\alpha} \leq 1$$

$$\frac{1}{r} \rightarrow \frac{1}{r} \Rightarrow \frac{1}{r} \rightarrow \frac{1}{r} \left(\frac{1}{r} - \frac{1}{r} \right) \frac{1}{r} \rightarrow \frac{1}{r} \left(\frac{1}{r} - \frac{1}{r} \right) \frac{1}{r} \frac{1}{r}$$

~~$\frac{1}{r}$~~

$$\text{so } \frac{1}{r} \rightarrow \frac{1}{r} \Rightarrow \frac{1}{r} \rightarrow \frac{1}{r} \Rightarrow \frac{1}{r} \left(\frac{1}{r} - \frac{1}{r} \right) \frac{1}{r} \Rightarrow \frac{1}{r} \left(\frac{1}{r} - \frac{1}{r} \right) \frac{1}{r} \frac{1}{r}$$

x^* strictly decreases with increasing r

$$\text{CRRA}(1) \rightarrow u(x) = \ln x$$

$$u'(x) = \frac{1}{x}, u''(x) = -x^{-2} < 0 \text{ for all } x$$

$$\text{FOC: } \cancel{\partial u(u(x)) / \partial x^*} |_{x=x^*} = \frac{2\alpha}{w+2x^*} - \frac{1-\alpha}{w-x^*} = 0$$

$$2\alpha(w-x^*) = (1-\alpha)(w+2x^*)$$

$$-2\alpha x^* + 2\alpha x^* = \cancel{2\alpha w} + (1-\alpha)w$$

$$-2\alpha x^* - (1-\alpha)2x^* = -2\alpha w + (1-\alpha)w$$

$$-2x^* = (1-3\alpha)w$$

$$x^* = \frac{3\alpha-1}{2} w$$

As $r \rightarrow 1$ from 0, $-1/r \rightarrow -1$ from $-\infty$

$$x^* = [(1-\alpha)^{-1/r} - (2\alpha)^{-1/r}]w / [(1-\alpha)^{-1/r} + 2(2\alpha)^{-1/r}]$$

$$\rightarrow [(1-\alpha)^{-1} - (2\alpha)^{-1}]w / [(1-\alpha)^{-1} + 2(2\alpha)^{-1}]$$

$$= [2\alpha(1-\alpha)/2\alpha(1-\alpha)]w / [2\alpha + 2(1-\alpha)/2\alpha(1-\alpha)]$$

$$= \frac{3\alpha-1}{2} w$$

~~So x^* decreases with increasing r for~~

So $x^*(r)$ is continuous for $r \in (0, 1]$ over the domain $r \in (0, 1]$, and x^* decreases with increasing r in this domain.

5a ~~for~~

Let F_x and F_y denote the cdf of X and the cdf of Y respectively.

$$V(a) = \int$$

Let D_x and D_y let D_x and D_y denote the domain of F_x and the domain of F_y respectively.

$$W(d) = \int_{x \in D_x} \int_{y \in D_y} f(x + (-d)y) F'_x(x) dx F'_y(y) dy$$

$$V(a) = \int_{x \in D_x} \int_{y \in D_y} dx + (-d)y F'_x(x) dy F'_y(y) dy$$

$$V'(a) = 0$$

$$V(d) = \int_{x \in D_x} \int_{y \in D_y} u(dx + (-d)y) F'_x(x) dx F'_y(y) dy$$

$$V'(d) = 0$$

$$\begin{aligned} b) V'(d) &= \int_{x \in D_x} \int_{y \in D_y} u'(dx + (-d)y) (x - y) F'_x(x) dx F'_y(y) dy \\ &= \int_{x \in D_x} \int_{y \in D_y} xu'(dx + (-d)y) - yu'(dx + (-d)y) F'_x(x) dx F'_y(y) dy \\ &= E(xu'(dx + (-d)y)) - E(yu'(dx + (-d)y)) \\ &= E(xu'(dx + (-d)y)) - E(yu'(dx + (-d)y)) \end{aligned}$$

~~All x and y from here on should instead be X and Y respectively~~

Suppose for reductio that $d=0$

$$\text{then } V'(d) = E(Xu'(x)) - E(Yu'(y))$$

$$= E(X)E(u'(y)) - E(Y)E(u'(y))$$

Since \rightarrow and y are independently distributed

$$Y, E(X)E(u'(y)) - E(Y)E(u'(y))$$

Since the agent is risk-averse so $u''(y) < 0 \Rightarrow$ then

$u'(y)$ is a decreasing function of y .

$$\stackrel{\text{def}}{=} 0$$

where $\stackrel{?}{=}$ follows from $X \perp\!\!\!\perp Y$, which implies $X \perp\!\!\!\perp u'(Y)$,

$\stackrel{?}{=}$ follows from the agents being risk averse which

implies $u'' < 0$, $u'(Y)$ is a decreasing function of

Y , $\text{cov}(Y, u'(Y)) = E(Yu'(Y)) - E(Y)E(u'(Y)) < 0$, and

$\stackrel{?}{=}$ follows from $E(X) = E(Y)$.

~~By re~~ # consequently, if $d=0$, $V'(d) \neq 0$

By symmetry, if $d=1$, $V'(d) \neq 0$

Then, $d \in (0, 1)$.

6a There is a discounted utility model that explains the given preferences since the given preferences do not violate only of completeness, transitivity, continuity, monotonicity in the first parameter and stationarity.

There is no discounted utility model that explains the given preferences since the given preferences violate stationarity. $(9,1) \succ (4,0)$ but $(9,2) \not\succ (4,1)$

$$b \quad u(9,1) = u(4,0)$$

$$\frac{1}{1+r} \sqrt{9} = \frac{1}{1+r^0} \sqrt{4}$$

$$3/1+r = 2/1$$

$$r=2$$

$$u(4,2) = u(1,0)$$

$$\frac{1}{1+r^2} \sqrt{4} = \frac{1}{1+r^0} \sqrt{1}$$

$$2/1+r^2 = 1/1$$

$$1+r^2=4, r^2=3, r=\sqrt{3}$$

Verifying that $u(x,t) = \frac{1}{1+r} + u(x)$ represents the given preferences

$$u(9,0) = 3/2$$

$$u(9,1) = 3/3 = 1$$

$$u(4,0) = 2/2 = 1$$

$$u(9,2) = 3/5$$

$$u(4,1) = 2/3$$

$$u(4,2) = 2/5$$

$$u(1,0) = 1/2$$

$$u(1,1) = 1/3$$

$$u(1,2) = 1/5$$
